A Lévy-Khintchine formula for $SU_q(N)$

According to the well-known Lévy-Khintchine formula, generators of Lévy processes on the Euclidean space are combinations of Gaussian parts and jump parts. A similar description for Lévy processes on Lie groups is provided by the Hunt formula. Going further with a generalization, to noncommutative Lévy processes on \ast -bialgebras, we still can characterize Lévy processes by their generators, but an analogous decomposition might not exist. In my talk, I will focus on the case of Lévy processes' generators on $SU_q(N)$, emphasizing the difference between $N=2$ and $N>2$.
